■ Experiment 1

Experiment Title: Implementation of a Singly Linked List for a Music Playlist

Objective

To implement a singly linked list in Python to manage a music playlist. The experiment demonstrates fundamental operations such as insertion at the beginning and end of the list, and displaying the playlist.

Algorithm

1. Define a `Node` class to store the song name and artist.
2. Define a `LinkedList` class to manage the playlist.
3. Implement the `insert_end` method to add songs at the end of the list.
4. Implement the `insert_beginning` method to add songs at the beginning of the list.
5. Implement the `display_songs` method to print the playlist.
6. Test the linked list by adding songs and displaying them.

Source Code

```

1 class Node:
2     def __init__(self, name, artist): # Fixed constructor method
3         self.name = name
4         self.artist = artist
5         self.next = None
6
7 class LinkedList:
8     def __init__(self, name=None, artist=None): # Fixed
9         constructor method
10        if name and artist:
11            self.head = Node(name, artist)
12        else:
13            self.head = None
14
15    def insert_end(self, name, artist):
16        new_song = Node(name, artist)
17        if not self.head:
18            self.head = new_song
19            return
20        current = self.head
21        while current.next:
22            current = current.next
23        current.next = new_song
24
25    def insert_beginning(self, name, artist):

```

```

25     new_song = Node(name, artist)
26     if not self.head:
27         self.head = new_song
28         return
29     new_song.next = self.head
30     self.head = new_song
31
32     def display_songs(self):
33         current = self.head
34         while current:
35             print(f"Name: {current.name}\\nArtist:
36                   {current.artist}\\n")
37             current = current.next
38
39 # Example Usage
40 if __name__ == "__main__":
41     playlist = LinkedList()
42     playlist.insert_end("Song1", "Artist1")
43     playlist.insert_end("Song2", "Artist2")
44     playlist.insert_beginning("Song3", "Artist3")
45     playlist.display_songs()

```

Output

```

Name: Song3
Artist: Artist3

```

```

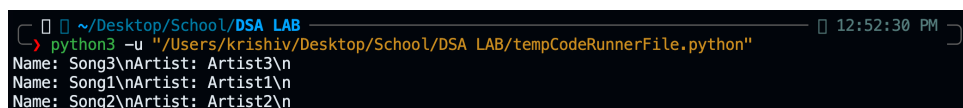

Name: Song1
Artist: Artist1

```

```

Name: Song2
Artist: Artist2

```

```

~/Desktop/School/DSA LAB 12:52:30 PM
python3 -u "/Users/krishiv/Desktop/School/DSA LAB/tempCodeRunnerFile.python"
Name: Song3\nArtist: Artist3\n
Name: Song1\nArtist: Artist1\n
Name: Song2\nArtist: Artist2\n

```

Figure 1: Sample output of the music playlist.

Conclusion

In this experiment, we successfully implemented a singly linked list to manage a music playlist. The linked list efficiently allows dynamic addition of songs at both the beginning and end of the playlist. This experiment highlights the advantages of linked lists over arrays, such as dynamic memory allocation and efficient insertion/deletion operations.

■ Experiment 2

Experiment Title: Implementation of Stack and Postfix Expression Evaluation

Objective

To implement the Stack data structure in Python and use it to evaluate a postfix arithmetic expression. The experiment demonstrates the fundamental operations of a stack and its application in expression evaluation.

Algorithm

1. Initialize an empty stack.
2. Read the input postfix expression.
3. For each character in the expression:
 - If the character is an operand, push it onto the stack.
 - If the character is an operator, pop the top two elements from the stack, apply the operator, and push the result back onto the stack.
4. Continue until the expression is fully processed.
5. The final result of the expression will be the last element remaining in the stack.

Source Code

```

1 class Stack:
2     def __init__(self):
3         self.items = []
4
5     def push(self, item):
6         self.items.append(item)
7
8     def pop(self):
9         if not self.is_empty():
10            return self.items.pop()
11
12    def is_empty(self):
13        return len(self.items) == 0
14
15    def peek(self):
16        if not self.is_empty():
17            return self.items[-1]
18
19    def evaluate_expression(self, expression):
20        operations = ('+', '-', '*', '/')
21
22        for char in expression:
23            if char not in operations:

```

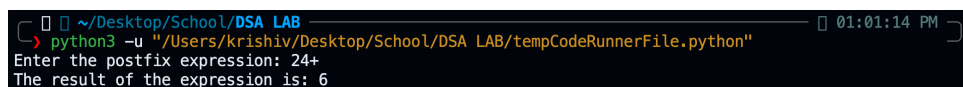

```

24         self.push(int(char)) # Convert character to
           integer before pushing
25     else:
26         operand_2 = self.pop()
27         operand_1 = self.pop()
28
29         if char == '+':
30             self.push(operand_1 + operand_2)
31         elif char == '-':
32             self.push(operand_1 - operand_2)
33         elif char == '*':
34             self.push(operand_1 * operand_2)
35         elif char == '/':
36             self.push(operand_1 / operand_2)
37
38     return self.pop()
39
40 # Example Usage
41 if __name__ == "__main__":
42     expression = input("Enter the postfix expression: ")
43     stack = Stack()
44     result = stack.evaluate_expression(expression)
45     print(f"The result of the expression is: {result}")

```

Output

Enter the postfix expression: 25+
The result of the expression is: 7

```

~/Desktop/School/DSA LAB 01:01:14 PM
> python3 -u "/Users/krishiv/Desktop/School/DSA LAB/tempCodeRunnerFile.py"
Enter the postfix expression: 24+
The result of the expression is: 6

```

Figure 2: Sample output of the postfix expression evaluation.

Conclusion

In this experiment, we successfully implemented a Stack data structure and used it to evaluate postfix expressions. The stack follows the Last-In-First-Out (LIFO) principle, making it suitable for managing operands and operators efficiently. The experiment also demonstrated the importance of stack operations in computational problem-solving.

■ Experiment 3

Experiment Title: Implementation of a Queue for a Ticket System

Objective

To implement a Queue data structure in Python using the `deque` class to manage a ticket system. The experiment demonstrates the First-In-First-Out (FIFO) principle and its application in processing customer support tickets.

Algorithm

1. Initialize an empty queue using `deque`.
2. Implement the `submit_ticket` method to add a ticket with customer name, issue description, and priority to the queue.
3. Implement the `display_tickets` method to show all tickets in the queue.
4. Implement the `process_tickets` method to process the first ticket in the queue (FIFO).
5. Test the queue by submitting tickets, displaying them, and processing them.

Source Code

```

1 from collections import deque
2
3 class TicketSystem:
4     def __init__(self):
5         self.tickets = deque()
6
7     def submit_ticket(self, name, issue_desc, priority = False):
8         ticket = {"Customer Name": name,
9                  "Issue Description": issue_desc,
10                 "Priority": priority}
11         self.tickets.append(ticket)
12
13     def display_tickets(self):
14         print("Current Tickets: ")
15         for i, ticket in enumerate(self.tickets, start = 1):
16             print(f"{i}. Customer Name: {ticket['Customer Name']}, Issue: {ticket['Issue Description']}, Priority: {ticket['Priority']}")
17
18     def process_tickets(self):
19         if not self.tickets:
20             print("No tickets to process.")
21             return
22         ticket = self.tickets.popleft()

```

```

23         print(f"\nProcessing ticket - Customer Name:
           {ticket['Customer Name']}, Issue: {ticket['Issue
           Description']}, Priority: {ticket['Priority']}")
24
25 if __name__ == '__main__':
26     ticket_system = TicketSystem()
27     ticket_system.submit_ticket("Name 1", "Issue 1", True)
28     ticket_system.submit_ticket("Name 2", "Issue 2", False)
29     ticket_system.display_tickets()
30     ticket_system.process_tickets()

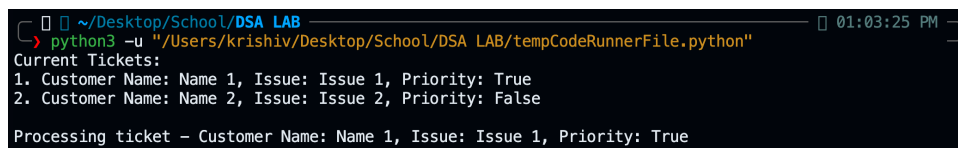

```

Output

Current Tickets:

1. Customer Name: Name 1, Issue: Issue 1, Priority: True
2. Customer Name: Name 2, Issue: Issue 2, Priority: False

Processing ticket - Customer Name: Name 1, Issue: Issue 1, Priority: True

```

~/Desktop/School/DSA LAB 01:03:25 PM
> python3 -u "/Users/krishiv/Desktop/School/DSA LAB/tempCodeRunnerFile.py"
Current Tickets:
1. Customer Name: Name 1, Issue: Issue 1, Priority: True
2. Customer Name: Name 2, Issue: Issue 2, Priority: False
Processing ticket - Customer Name: Name 1, Issue: Issue 1, Priority: True

```

Figure 3: Sample output of the ticket system queue.

Conclusion

In this experiment, we successfully implemented a Queue data structure using Python's `deque` to manage a ticket system. The queue effectively followed the First-In-First-Out (FIFO) principle, ensuring tickets were processed in the order they were received. This experiment demonstrated the practical utility of queues in real-world applications like customer support systems, where fair and orderly processing is essential.
